

INTERNSHIP REPORT

Deloitte Australia – Data Analytics Job Simulation

Submitted by

AMAN KUMAR

College	IILM University, Greater Noida
Course	B.Tech CSE (Cloud Computing)
Session	2023 – 2027
Year / Semester	4th Year, 7th Semester
Roll No.	CS-2341531
Organisation	Deloitte Australia (via Forage)
Simulation	Data Analytics Job Simulation
Date of Completion	29h August 2026

1. Introduction

This report documents my participation in the Deloitte Australia Data Analytics Job Simulation, completed through Forage during August 2026. The simulation is designed to give students a risk-free, self-paced experience of the kind of work performed by Deloitte's forensic and data analytics teams, using realistic tasks, sample datasets, and example solutions from Deloitte professionals.

Deloitte describes itself not merely as a professional services firm but as a group of professionals working on some of the biggest challenges facing organisations and society today, spanning audit, consulting, risk advisory, and forensic services. The simulation offered a practical introduction to two such areas: data analysis and forensic technology, and was structured around two guided tasks.

2. About the Job Simulation

The Job Simulation is a self-paced, non-graded programme that takes approximately 1-2 hours to complete in total. It does not involve live sessions or formal assessments; instead, each task is guided by pre-recorded videos and example answers provided by the Deloitte Australia team, and participants are free to attempt the tasks in their own time.

On successful completion, participants receive the following:

- A Certificate of Completion, which can be added to a resume or LinkedIn profile.
- A Resume Snippet describing the skills demonstrated.
- Interview Tips to help articulate the experience in interviews.
- Practical exposure to in-demand Skills, including data analysis, data modelling, data visualisation tools, and spreadsheet skills.

3. Task 1 – Data Analysis

The first task required building a dashboard to explore telemetry data belonging to a fictional client, Daikibo Robotics, using Tableau. The objective was to learn how to use Tableau to visualise operational data and identify patterns across the client's global manufacturing footprint.

The dataset consisted of over 160,000 individual device telemetry records collected from Internet-of-Things sensors installed on factory equipment. Each record captured a device ID, device type (such as CNC machines, conveyors, furnaces, heavy presses, laser cutters, metal presses, and spot welders), a timestamp, the device's location (country, city, area, factory, and section), and its operational data, including health status and temperature.

Using this data, I built a two-part dashboard in Tableau:

- A bar chart showing the count of “unhealthy” device readings grouped by factory, covering Daikibo's sites in Berlin, Meiyo, Sendai, and Shenzhen.
- A second bar chart breaking down “unhealthy” readings by device type, to identify which categories of machinery were most frequently flagged.

This view made it possible to see at a glance that the Shenzhen and Sendai factories reported a noticeably higher volume of unhealthy readings than the other sites, and that laser cutters accounted for a disproportionately large share of the unhealthy readings across device types — the kind of pattern that would prompt further investigation in a real client engagement. A screenshot of the completed dashboard is included below.

Figure 1: Tableau dashboard – unhealthy device readings by factory and device type.

4. Task 2 – Forensic Technology

The second task placed me on a forensic technology team investigating a potential unfair pay issue at one of Daikibo's factories. The objective was to help a client draw conclusions from data by classifying rows in an Excel spreadsheet based on a calculated “equality score” for each job role.

I added a classification column to the provided spreadsheet, categorising each job role — from Sr. Engineer up to C-Level positions — into equality classes such as “Fair,” “Unfair,” and “Highly Discriminative,” based on the equality score assigned to that role. Roles with strongly negative scores, particularly at senior levels such as C-Level, VP, and Director, were classified as “Highly Discriminative” or “Unfair,” while roles closer to a neutral score were classified as “Fair.”

This exercise demonstrated how forensic technology teams use structured classification logic on top of raw HR or payroll data to surface potential pay equity issues, turning a spreadsheet of scores into an actionable, client-ready conclusion.

5. Reflections and Learnings

This simulation gave me a hands-on, if compact, introduction to how data analytics and forensic technology work is actually done in a professional services setting, rather than just reading about it in theory. Working with a genuinely large telemetry dataset in Task 1 pushed me to think about how raw sensor data needs to be filtered, grouped, and visualised before it becomes useful — a single number in isolation means very little, but the same numbers grouped by factory or device type in a Tableau dashboard immediately point to where a problem is worth investigating.

Building the dashboard also gave me practical, applied experience with Tableau as a data visualisation tool — choosing the right chart type, structuring a dashboard with multiple views, and presenting operational data in a way that a non-technical stakeholder could interpret at a glance. Task 2 complemented this with a more analytical, spreadsheet-based skill: constructing a classification logic in Excel and applying it consistently across a dataset to turn a numeric “equality score” into a clear, defensible conclusion about pay fairness.

Together, the two tasks helped me build and practise data analysis, data modelling, data visualisation, and spreadsheet skills in a realistic client context, and gave me a clearer sense of how a forensic/data analytics team moves from a raw dataset to an insight that a client can actually act on. As a Computer Science (Cybersecurity) student, I found it particularly useful to see how the same instincts I use for examining logs and datasets in a

security context — looking for anomalies, outliers, and patterns — apply equally well to business and forensic data analysis.

6. Conclusion

The Deloitte Australia Data Analytics Job Simulation was a short but effective way to gain exposure to the kind of work performed by Deloitte's forensic and analytics professionals. Completing the two tasks — building a Tableau dashboard from IoT telemetry data and classifying pay equity data in Excel — strengthened my practical skills in data analysis, data visualisation, and spreadsheet-based problem solving, and gave me a clearer picture of a career path in data analytics and forensic technology.
